**ABSTRACT:** A novel 1,7-palladium migration—cyclization—dealkylation sequence for the regioselective synthesis of benzotriazoles has been developed. These reactions proceed in excellent yields with high regioselectivities. The mechanism of the reaction has also been investigated.

Because of their interesting structures, high reactivity, and anticancer properties, N-substituted benzotriazoles are widely used in synthetic organic chemistry, materials science, and pharmaceutical science. For example, benzotriazole 1 is an inhibitor of c-Kit protooncogene and exists as either the N1-, N2-, or N3-substituted isomer (Scheme 1). N-Substituted benzotriazoles can be prepared by copper-catalyzed Buchwald–Hartwig-type reactions, a transition-metal-free procedure using aryne chemistry for N-arylation, the [3 + 2] cycloaddition reaction between arynes and organic azides, and the reaction of (Z)-1-aryl-3-hexen-1,5-dienes with sodium azide. However, the products are formed as a mixture of N1-, N2-, and N3-arylation isomers in all cases except the synthesis involving Buchwald–Hartwig-type reactions.

Larock and Gallagher recently reported the 1,4-palladium migration for the synthesis of fused polycycles. This process involves a Pd-catalyzed C–H activation proceeding via a key five-membered-ring palladacycle intermediate. Aryltriazenes are unique compounds that have been used in medicinal chemistry, combinatorial chemistry, organic synthesis, and molecular architectures synthesis and as precursors to heterocycles. Herein we report a regioselective synthesis of benzotriazoles from aryltriazenes via a novel 1,7-palladium migration and intramolecular amination—dealkylation sequence.

When R = H, the cis/trans isomerization of 1,3-diphenytriazone occurs under basic conditions. Thus, heating triazene 2aa in the presence of Pd(0Ac)2 gave the direct amination product 4a in 96% yield. We envisioned that if the H were to be replaced by an alkyl group, the reaction of triazene 2a (with R = Me) would give benzotriazole 3a via a 1,7-palladium migration—cyclization—dealkylation sequence involving a C–H activation (Scheme 2).

To probe the viability of this envisioned intramolecular 1,7-palladium migration and the subsequent amination reaction, palladium complexes derived from various ligands and bases were screened in toluene or N,N-dimethylformamide (DMF). The results are summarized in Table 1. The desired benzotriazole 3a was obtained in a trace amount with Cs2CO3 as the base and dppp as the ligand in toluene or DMF (Table 1, entries 1 and 7). After the base was changed from Cs2CO3 to K2CO3, 3a was formed in 64% yield (entry 2). Both bidentate ligands such as dppb, dppe, dppp, and dppf (entries 3–5 and 9) and a monophosphorus ligand (PPh3, entry 6) led to the formation of compound 3a in 31–75% yield using toluene as solvent. The best result was obtained with dppp as the ligand in the presence of KOAc as the base and DMF as the solvent (entry 8).

To explore the reaction scope, a number of 3-methyl-1,3-diphenytriazenes 2b–2p were examined under the optimal reaction conditions. The substituents on the two aromatic groups had different effects on the yields (3b–3p in Table 2). Electron-donating groups on the bromo-substituted aromatic ring (shown in red) decreased the yield (3i, 3o, and 3p; the yield could be improved by running the reaction at high temperature), while on the other aromatic system (shown in blue), the yields increased to up to 98% (3n) under the optimal reaction conditions. The
structure of \(3h\) was determined by X-ray analysis (see the Supporting Information). Lower yields were obtained when steric hindrance was introduced near the reaction site (\(3k\) and \(3m\)), and higher temperatures gave better yields. Gratifyingly, \(1\)-(4-methoxyphenyl)-1\(H\)-benzotriazole-5-carboxylic acid ethyl ester (\(3o\)), the important intermediate leading to benzotriazole \(1\), was obtained in 80% yield after treatment with Pd(OAc)\(_2\) and dppp at 150 °C. Furthermore, we also used substrates with groups other than Me on the triazene motif. All of the substrates with alkyl groups such as Et, \(n\)-Bu, \(i\)-Pr, and Bn gave the desired product \(3a\) in good yields from 43 to 76% (Scheme 3). Even with a very bulky group like \(t\)-Bu, the desired product was obtained in 59% yield. However, N-phenyl-triazene (\(2v\)) did not produce the desired product \(3a\).

To probe the reaction mechanism, substrate \(5a\) was subjected to the standard reaction conditions, and N-substituted benzotriazole \(3a\) was formed in 97% yield. This result strongly indicates that the same intermediate is formed when the substrates \(2a\) and \(5a\) are treated with Pd(OAc)\(_2\) in the presence of base and ligand. When we changed the base to potassium laurate, the byproduct methyl laurate was observed along with \(3a\) using GC-MS analysis. Furthermore, \(d_5\)-triazene \(6a\) was synthesized and subjected to the standard reaction conditions (using toluene as the solvent), and 83% deuterium incorporation at the ortho position of \(7a\) was observed using \(^1\)H NMR and GC-MS analysis (Scheme 4). On the basis of these results, a plausible reaction mechanism for this fascinating process is depicted in Scheme 5. Presumably, Pd(0) would first undergo oxidative addition to bromotriazine.
In conclusion, we have developed a novel 1,7-palladium migration–cyclization–dealkylation sequence (The Coordinated Ligand Has Been Omitted for Clarity). After N₂ reductive elimination, giving /C₀/C₀ under H bond activation and H bond of the other aromatic ring close enough possible and cannot be excluded on the basis of the present results, especially for the t-Bu-substituted substrates. Migration and cyclization reactions, see: (b) Kale, R. R.; Prasad, V.; Hussain, H. A.; Tiwari, V. K. Tetrahedron Lett. 2010, 51, 5740. (c) Liu, Q.; Wen, D.; Hao, G.; Li, Q.; Zhu, Y. Helv. Chim. Acta 2010, 93, 1350.

In conclusion, we have developed a novel 1,7-palladium migration–cyclization–dealkylation sequence for the regioselective synthesis of benzotriazoles. These reactions occurred in excellent yields with high regioselectivities. Further investigations of the mechanism and synthetic applications are underway.
